In many cells, mRNAs containing inverted repeated *Alu* elements (*IRAlus*) in their 3' untranslated regions (UTRs) are inefficiently exported to the cytoplasm. Such nuclear retention correlates with paraspeckle-associated protein complexes containing p54<sup>nrb</sup>. However, nuclear retention of mRNAs containing *IRAlus* is variable, and how regulation of retention and export is achieved is poorly understood. Here we show one mechanism of such regulation via the arginine methyltransferase CARM1 (coactivator-associated arginine methyltransferase 1). We demonstrate that disruption of CARM1 enhances the nuclear retention of mRNAs containing *IRAlus*. CARM1 regulates this nuclear retention pathway at two levels: CARM1 methylates the coiled-coil domain of p54<sup>nrb</sup>, resulting in reduced binding of p54<sup>nrb</sup> to mRNAs containing *IRAlus*, and also acts as a transcription regulator to suppress *NEAT1* transcription, leading to reduced paraspeckle formation. These actions of CARM1 work together synergistically to regulate the export of transcripts containing *IRAlus* from paraspeckles under certain cellular stresses, such as poly(I:C) treatment. This work demonstrates how a post-translational modification of an RNA-binding protein affects protein-RNA interaction and also uncovers a mechanism of transcriptional regulation of the long noncoding RNA *NEAT1*.

Supplemental material is available for this article.

Received December 8, 2014; revised version accepted February 13, 2015.

The mammalian nucleus is highly organized into chromosome territories and a number of distinct membrane-less nuclear bodies or subnuclear structures that can affect nuclear neighborhoods and gene regulation (Zhao et al. 2009). Distinct nuclear bodies contain specific protein and RNA components that define particular nuclear processes (Mao et al. 2011b).

Paraspeckles, first identified in 2002 (Fox et al. 2002), are composed of the long noncoding RNA (lncRNA) *NEAT1*, which confers structural integrity and multiple proteins for its potential functions (Prasanth et al. 2005; Chen et al. 2008; Chen and Carmichael 2009; Clemson et al. 2009; Sasaki et al. 2009; Sunwoo et al. 2009; Naganuma et al. 2012). There are two isoforms of *NEAT1*

lncRNAs, *NEAT1\_v1* and *NEAT1\_v2*, produced by alternative 3' end processing (Naganuma et al. 2012). A live-cell imaging system aiming to visualize the inducible transcription of *NEAT1* lncRNAs and paraspeckle proteins revealed that both the active transcription of *NEAT1* and *NEAT1* lncRNAs regulate paraspeckle maintenance and dynamics (Mao et al. 2011a). In addition to several well-studied *Drosophila* behavior and human splicing (DBHS) family proteins (including PSP1 $\alpha$ , p54<sup>nrb</sup>, and PSF, which were known to be localized to paraspeckles) (Fox et al. 2002, 2005; Bond and Fox 2009), new paraspeckle proteins (including many RNA-binding

proteins) were recently identified (Naganuma et al. 2012; West et al. 2014).

Recent studies have revealed that both *NEAT1* lncRNAs and paraspeckle proteins can mediate the function of paraspeckles in gene regulation, although the detailed mechanisms remain to be fully defined. For example, the abundant *NEAT1* RNA was shown to regulate transcription by sequestering the paraspeckle protein PSF (Hirose et al. 2014; Imamura et al. 2014). Such sequestration of the transcriptional repressor PSF resulted in the activation of IL8 expression upon immune stimuli (Imamura et al. 2014) and *ADARB2* transcription (Hirose et al. 2014). Moreover, genome-wide analyses recently revealed that *NEAT1* can associate with hundreds of active chromatin sites (West et al. 2014), consistent with the view that paraspeckles may be involved in transcription regulation.

In addition to *NEAT1*-mediated regulation, p54<sup>nrb</sup> is involved in the paraspeckle-mediated nuclear retention of mRNAs containing inverted repeats in their 3' untranslated regions (UTRs) (Prasanth et al. 2005; Chen et al. 2008; Chen and Carmichael 2009; Mao et al. 2011a; Elbarbary et al. 2013). The mouse *CTN-RNA*, which contains a dsRNA structure resulting from inverted short interspersed nuclear elements (SINEs) in its 3' UTR, is retained in the nucleus and at least partially localized to paraspeckles (Prasanth et al. 2005). In human cells, hundreds of genes contain inverted repeated SINEs (mainly *Alu* elements) in their 3' UTRs. *Alu* elements are unique to primates and account for almost all of the human SINEs and >10% of the genome. Their abundance leads to the frequent occurrence of inverted repeat structures (inverted repeated *Alu* elements [*IRAlus*]) in gene regions (Chen and Carmichael 2008). We reported previously that mRNAs containing *IRAlus* in their 3' UTRs are retained in the nucleus in paraspeckles and in association with p54<sup>nrb</sup> (Chen et al. 2008; Chen and Carmichael 2009). Such regulation at paraspeckles in human cells was further demonstrated by live-cell imaging (Mao et al. 2011a). Therefore, this nuclear retention pathway of *IRAlus* in 3' UTRs of genes provides an additional layer of gene regulation by sequestering otherwise mature mRNAs within the nucleus.

Interestingly, we and others observed that the nuclear retention of transcripts containing *IRAlus* is variable, with some such mRNAs located in the nucleus, while others are in the cytoplasm (Chen and Carmichael 2008; Chen et al. 2008; Hundley et al. 2008; Elbarbary et al. 2013). How is such nuclear retention of mRNAs containing *IRAlus* at paraspeckles achieved and regulated? Earlier observations suggested that the mouse *CTN-RNA* is retained in the nucleus until cell stress occurs, resulting in the cleavage and removal of its 3' UTR nuclear retention signal (inverted repeats of murine SINEs) by an unknown mechanism. The truncated message is then transported efficiently to the cytoplasm for translation (Prasanth et al. 2005). However, some mRNAs containing *IRAlus* were seen in the cytoplasm (Chen et al. 2008; Hundley et al. 2008; Elbarbary et al. 2013), implying that other mechanisms may be involved in the release of

paraspeckle-mediated nuclear retention of mRNAs containing *IRAlus*. For instance, it had been shown recently that the dsRNA-binding protein Staufen 1 competed with p54<sup>nrb</sup> for the binding to 3' UTR *IRAlus*, resulting in an enhanced nuclear export and translation of these RNAs (Elbarbary et al. 2013). Another hypothesis is that post-translational modifications on p54<sup>nrb</sup> could alter its binding activity to mRNAs containing *IRAlus*.

CARM1 (coactivator-associated arginine methyltransferase), also known as PRMT4, was the first identified nuclear receptor coactivator in a family of nine PRMT members (PRMT1–9) (Bedford and Clarke 2009). CARM1 methylates histone H3 at Arg17, generating a docking site for the recruitment of the methylarginine effector TDRD3 (Yang et al. 2010). CARM1 also methylates many nonhistone proteins that play important roles in a number of biological processes, including transcriptional regulation (Chen et al. 1999), mRNA splicing (Cheng et al. 2007), muscle differentiation (Chen et al. 2002), adipocyte differentiation (Yadav et al. 2008), and T-cell development (Li et al. 2013).

Here we describe a new mechanism of gene regulation by CARM1. Disruption of CARM1 significantly enhances the nuclear retention of mRNAs containing *IRAlus*. We demonstrate that CARM1 regulates the nuclear retention of mRNAs containing *IRAlus* in paraspeckles at two levels. On the one hand, CARM1 methylates p54<sup>nrb</sup>, resulting in the reduced binding capability to mRNAs containing *IRAlus*; on the other hand, CARM1 suppresses *NEAT1* transcription and paraspeckle formation. Actions of CARM1 at these two levels synergistically work together to regulate the export of transcripts containing *IRAlus* from paraspeckles under certain cellular stresses, such as poly(I:C) treatment. This represents one of a few examples where post-translational modification of an RNA-binding protein affects protein–RNA interaction and gene regulation. In addition, it shows how transcriptional regulation of the lncRNA *NEAT1* can occur.

## Results

### *p54<sup>nrb</sup> is methylated by CARM1*

Very few substrates for CARM1 have been characterized, which limits the understanding of the roles of this enzyme. The identification of the repertoire of substrates for CARM1 is an essential step toward a complete understanding of its biological functions. CARM1 substrates are methylated in wild-type mouse embryonic fibroblast (MEF) cells but remain unmethylated in CARM1 knockout cells. Thus, the CARM1 knockout nuclear extracts are good substrates for in vitro methylation assays that would allow the identification of additional CARM1 substrates. We performed in vitro methylation assays using acid-extracted histones from the nuclei of wild-type and CARM1<sup>-/-</sup> MEFs as substrates and GST-CARM1 as an enzyme. The reaction mixtures were then run on an SDS-PAGE gel, and the indicated protein bands corresponding to potential CARM1 substrates were used for trypsin digestion and subsequent mass spectrometry (MS). Of

the six identified substrates found in duplicated experiments, PABP1 (Lee and Bedford 2002) and SmB (Cheng et al. 2007) were previously described as CARM1 substrates. Interestingly, p54<sup>nrb</sup>, the well-known paraspeckle component, was also identified as a new CARM1 substrate and was chosen for further study (Fig. 1A).

p54<sup>nrb</sup> as a substrate of CARM1 was further validated by CARM1 in vitro methylation of *Escherichia coli*-expressed histidine-tagged p54<sup>nrb</sup> (Fig. 1B). Furthermore, a pan-screening for the activity of arginine methylase family members on p54<sup>nrb</sup> revealed that PRMT1 and PRMT6 could also methylate p54<sup>nrb</sup>, but the reaction of CARM1 on p54<sup>nrb</sup> was the strongest (Supplemental Fig. S1A). Moreover, the in vitro methylation of p54<sup>nrb</sup> truncations revealed that multiple arginine methylation sites on p54<sup>nrb</sup> were enriched in the coiled-coil domain and the C-terminal region of the protein (Supplemental Fig. S1B).

To identify the specific methylation sites catalyzed by CARM1, we developed CARM1 knockdown HeLa and HEK293 cell lines (Supplemental Fig. S2A). Flag-tagged p54<sup>nrb</sup> was expressed in scramble shRNA-treated (scramble) and CARM1 shRNA-treated (CARM1 knockdown) cell lines, and then immunoprecipitation by anti-Flag was performed (Supplemental Fig. S2B) followed by MS analysis. Multiple methylation sites in p54<sup>nrb</sup> were identified from MS (Supplemental Fig. S2C). Among these sites, R357, R365, and R378 were present in the anti-Flag precipitated complex in scramble cell lines but little in CARM1 knockdown cell lines (Supplemental Fig. S2D; data not shown), confirming that they are CARM1-methylated sites on p54<sup>nrb</sup>. In vitro methylation assays of p54<sup>nrb</sup> mutants in which these arginines were replaced with lysines further confirmed that R357, R365, and R378 were the major sites methylated by CARM1 (Fig. 1C).

**Figure 1.** p54<sup>nrb</sup> is methylated by CARM1. (A) p54<sup>nrb</sup> is a CARM1 substrate. Acid-extracted histones from CARM1 wild-type (wt; +/+) and knockout (-/-) MEFs were used as substrates, and GST-CARM1 was used as an enzyme to perform standard in vitro methylation assays. Reactions were done in duplicate, separated on SDS-PAGE, and transferred to PVDF membranes for fluorography and Ruby staining. The indicated methylated proteins were processed for protein identification using MS. (B) p54<sup>nrb</sup> is methylated in vitro by recombinant CARM1. In vitro methylation reactions were performed using recombinant His-tagged p54<sup>nrb</sup> with recombinant GST-CARM1 in the presence of [<sup>3</sup>H]AdoMet. Reactions were separated on SDS-PAGE and transferred to PVDF membranes for fluorography, Coomassie blue gel staining, and immunoblotting with anti-His antibody. (C) Lysine replacement of Arg357 and Arg365 (R357K, 365K) and of Arg378 and Arg383 (R378K, 383K) reduces p54<sup>nrb</sup> methylation. Mutants of p54<sup>nrb</sup> were made as indicated by MS results and expressed as His-tagged fusion proteins. Purified His-p54<sup>nrb</sup> mutants were incubated with GST-CARM1 in the presence of [<sup>3</sup>H]AdoMet. Methylated proteins were separated by SDS-PAGE and visualized by fluorography. The same membrane was subjected to Ponceau staining to verify equal loading. Note that R383 was not identified by MS

but was included in the mutation assay. (D) p54<sup>nrb</sup> interacts with CARM1. HeLa cells expressing Flag-p54<sup>nrb</sup> or Flag-EGFP (control) were immunoprecipitated with anti-Flag antibody and then immunoblotted with anti-Flag, anti-p54<sup>nrb</sup>, anti-PSF, anti-CARM1, and anti-PRMT6. Note that p54<sup>nrb</sup> specifically interacted with CARM1 but not PRMT6 in vivo. (IgGH) IgG heavy chain; (IgGL) IgG light chain. (E) RNA-independent interaction of p54<sup>nrb</sup> and CARM1 in HeLa cells. Total extracts of HeLa cells treated with RNase A were immunoprecipitated with CARM1 antibody or mock antibody and then immunoblotted with anti-CARM1 and anti-p54<sup>nrb</sup>. (F) p54<sup>nrb</sup> and CARM1 colocalize in HeLa cells. HeLa cells were stained with anti-p54<sup>nrb</sup> and anti-CARM1 antibodies. DAPI was used to indicate DNA. (G) CARM1 is a new component of paraspeckles. RNA in situ hybridization (ISH) was performed with digoxigenin (Dig)-labeled antisense *NEAT1* probe (green) in HeLa cells, and representative images are shown. CARM1 and p54<sup>nrb</sup> are in red. *NEAT1* colocalizes with CARM1 (top panels) and p54<sup>nrb</sup> (bottom panels).

The coimmunoprecipitation (co-IP) assays between p54<sup>nrb</sup> and CARM1 performed in HeLa (Fig. 1D,E) and HEK293 (data not shown) cells both revealed that they interacted with each other endogenously. CARM1 was detected in the Flag-p54<sup>nrb</sup> immunoprecipitation complexes and vice versa (Fig. 1D,E). Importantly, the co-IP was still detectable in the presence of RNase A (Fig. 1E). Colocalization of the endogenous p54<sup>nrb</sup> and CARM1 further revealed that they colocalized in the nucleus in HeLa cells (Fig. 1F) and largely within paraspeckles, as revealed by *NEAT1* RNA in situ hybridization (ISH) and CARM1 immunostaining (Fig. 1G). Together, these results suggest that p54<sup>nrb</sup> is a new substrate for CARM1 and that p54<sup>nrb</sup> methylation by CARM1 may occur within paraspeckles.

#### *CARM1 deficiency leads to enhanced nuclear retention of mRNAs containing IRAlus*

We next asked whether p54<sup>nrb</sup> methylation by CARM1 could alter paraspeckle-associated p54<sup>nrb</sup> function. Since p54<sup>nrb</sup> is involved in the nuclear retention of mRNAs containing *IRAlus* in their 3' UTRs (mRNA-*IRAlus*) (Chen et al. 2008; Mao et al. 2011a), we first performed mRNA nuclear retention assays in the scramble and CARM1 knockdown cell lines with mRNA-*IRAlus* reporter constructs as previously described (Chen et al. 2008). Constructs with a single *Alu* element or *IRAlus* (originally from the 3' UTR of the *Nicn1* gene) in the 3' UTR of *egfp* mRNA were individually transfected into the scramble and CARM1 knockdown HeLa cells. Consistent with previous reports (Chen et al. 2008; Mao et al. 2011a), the expression of EGFP protein was repressed by *IRAlus*, but not by a single *Alu*, in the 3' UTR of *egfp* (Fig. 2A,B). This repressed EGFP expression was largely due to the nuclear retention of *egfp-IRAlus* (Fig. 2A,B).

Strikingly, the EGFP fluorescence in CARM1 knockdown cells transfected with the EGFP-*IRAlus* construct was much more significantly reduced than that in scramble cells (Fig. 2A). This enhanced repression effect was also confirmed by Western blotting with anti-GFP antibody (Fig. 2A, top right panels, lanes 2,4). Meanwhile, Northern blotting of transcripts of *egfp* from the same batch of transfected HeLa cells revealed that both transfections yielded comparable or higher levels of *egfp* mRNAs (Fig. 2A, bottom right panels, lanes 2,4), suggesting that the observed enhanced EGFP expression repression in CARM1 knockdown cells is post-transcriptional. We also observed similar phenomena using other constructs containing inserts of a single *Alu* element or *IRAlus* derived from the 3' UTR of the *Lin28* gene in the 3' UTR of *egfp* mRNA (Supplemental Fig. S3A,B) and in other cell lines, such as in the scramble and CARM1 stable knockdown HEK293 cells (Supplemental Fig. S4A,B).

What mechanism accounts for reduced EGFP expression in CARM1 knockdown cells? Further analyses revealed that CARM1 knockdown strikingly enhanced the sequestration of mRNAs containing 3' UTR *IRAlus*

in the nucleus. First, nuclear/cytoplasmic (N/C) RNA fractionation analyses in scramble and CARM1 knockdown cells individually transfected with *egfp-Alu* or *egfp-IRAlus* constructs clearly showed that *egfp-IRAlus* mRNA was more efficiently retained in the nuclei of CARM1 knockdown cells than those in the nuclei of scramble cells (Fig. 2B, left panels [lanes 3,4,7,8] and right panel), while the N/C ratio of *egfp-Alu* mRNA was not altered (Fig. 2B, left panels [lanes 1,2,5,6] and right panel). Second, visualization of the subcellular distribution of *egfp-IRAlus* in scramble and CARM1 knockdown cells by RNA ISH at the single-cell level revealed that *egfp* mRNAs with *IRAlus* were more highly enriched in the nucleus in CARM1 knockdown cells than those in scramble cells (Fig. 2C). Third, if CARM1 were essential for the paraspeckle-associated mRNA-*IRAlus* nuclear retention, we would expect to observe that the endogenous mRNA-*IRAlus* would have a different fate in CARM1 depletion cells. There are hundreds of mRNAs containing *IRAlus* in their 3' UTRs (Chen et al. 2008), and we chose a number of mRNAs that contain *IRAlus* in their 3' UTRs and are expressed well in HeLa and HEK293 cells (*nicn1*, *icmt*, *mrpl30*, and *pccb*) (Supplemental Fig. S5). For each of these mRNAs, CARM1 knockdown resulted in more efficient retention in the nucleus in both cell lines (Fig. 2D,E; Supplemental Figs. S4D, S6), while the N/C distribution of *actin* mRNA remained unchanged. For experiments shown in these figures, we used PCR probes that specifically recognize mRNAs with the extended 3' UTRs that contain *IRAlus* (Supplemental Fig. S5). Note that the longer isoform of each of the mRNAs containing *IRAlus* examined increased its N/C ratio after knockdown of CARM1 (Fig. 2D; Supplemental Figs. S4D, S6A). We further used Northern blotting to confirm the subcellular distribution of two such endogenous mRNAs: *nicn1* (Fig. 2E) and *icmt* (Supplemental Fig. S6B). The long isoform of *nicn1* contains one pair of *IRAlus* in its 3' UTR, but the short isoform lacks *IRAlus*. Correspondingly, the *nicn1* long isoform is preferentially localized to the nucleus, while the short one is almost exclusively cytoplasmic (Fig. 2E; Chen et al. 2008). Importantly, knockdown of CARM1 increased the amount of *nicn1* long isoform retained in the nucleus (Fig. 2E), while the subcellular distribution of the *nicn1* short isoform and *actin* mRNA remained unaltered (Fig. 2E). Such altered nuclear retention regulation by CARM1 was also seen in another examined endogenous mRNA, *icmt* (Supplemental Fig. S6B), by Northern blotting. Together, these results demonstrate that the absence of CARM1 leads to an enhanced nuclear retention of mRNAs containing 3' UTR *IRAlus*.

Recently, *NEAT1* was shown to bind to hundreds of active chromatin sites in MCF7 cells (West et al. 2014). We found that ~40% of such genes contain at least one pair of *IRAlus* in their 3' UTRs expressed in MCF7 cells (Fig. 2F), implying that these transcribed nascent RNAs and corresponding mRNAs with 3' UTR *IRAlus* are located close to paraspeckles and thus are capable of association with paraspeckle protein p54<sup>nrb</sup> for their nuclear retention.

**Figure 2.** CARM1 deficiency enhances nuclear retention of mRNAs containing IRAlus. (A) CARM1 knockdown (KD) suppresses EGFP expression of *egfp* mRNA containing IRAlus in its 3' UTR. (Left) IRAlus and *Alu* from the 3' UTR of *Nicn1* were inserted into the 3' UTR of *egfp* mRNA (Chen et al. 2008). Stable HeLa cell lines with the scramble shRNA treatment and CARM1 knockdown were transfected with the indicated plasmids, and fluorescence was observed 24 h after transfection. (FL) Fluorescence; (BF) bright field. (Middle) The expression of EGFP and transcripts of *egfp* from the same batch of transfected HeLa cells as described in the left panels was investigated by Western blotting by probing with anti-EGFP antibody and by Northern blotting by probing with a Dig-labeled *egfp* fragment. Actin was used as loading control for Western blotting. Equivalent amounts of total RNAs were loaded for Northern blotting as indicated by 28S and 18S rRNAs. (Right) The relative translation efficiency (the relative intensity of each corresponding band from Western blotting and Northern blotting shown in the middle panels) of *egfp-Alu* mRNA and mRNA with *egfp-IRAlus* in scramble and CARM1 knockdown cells. (B) CARM1 deficiency significantly enhances the nuclear retention of *egfp* mRNA with IRAlus. (Left) Cytoplasmic and nuclear RNAs were isolated from the same batch of transfected HeLa cells used in A and then resolved on a denaturing agarose gel. Transcripts of *egfp*-tagged RNAs were probed with a Dig-labeled *egfp* fragment. *tRNA<sup>lys</sup>* and 45S rRNA were used as markers for cytoplasmic/nuclear RNA isolation. Equivalent amounts of RNAs from different subcellular compartments were loaded as indicated by 28S and 18S

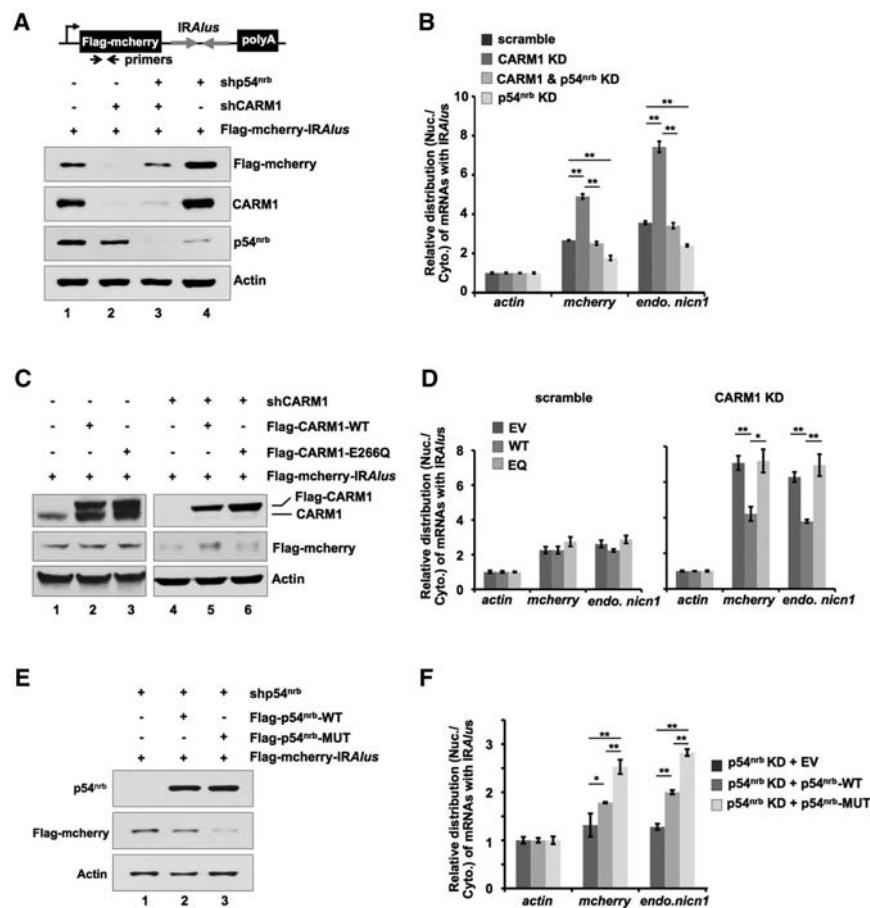

rRNAs. (Right) The relative subcellular distribution of RNAs with IRAlus or single *Alu*-containing RNAs was quantified from the left panels by ImageJ and normalized to the relative amount of *tRNA<sup>lys</sup>*. The ratio was obtained by comparing the value of each nuclear-retained fractionation with those of the cytoplasmic distributed RNAs. (C) Enhanced *egfp* mRNAs with IRAlus are retained in the nucleus upon CARM1 deficiency, as revealed by RNA ISH. (Left) The *egfp* mRNAs with IRAlus were probed with a Dig-labeled antisense *egfp* probe in HeLa cells transfected with the indicated plasmids, and representative images are shown. The white dotted line indicates the nucleus. (Right) Statistical analysis of the left panel. More than 300 transfected cells were analyzed after each transfection, and the *P*-value from a one-tailed *t*-test in the pairwise comparison is shown. (D) CARM1 knockdown enhances the nuclear retention of other endogenous mRNAs with IRAlus. RT-qPCR analyzed a number of other endogenous mRNAs with IRAlus using nuclear and cytoplasmic fractionated RNAs. Primers to detect RNAs with IRAlus were designed downstream from IRAlus in 3' UTRs (Supplemental Fig. S5). The relative subcellular distribution of each RNA with IRAlus was normalized to the relative amount of *actin* mRNA. (E) CARM1 knockdown promotes the nuclear retention of endogenous *nicn1* mRNA in HEK293 cells. (Top) A schematic drawing of transcripts of the *Nicn1* gene containing two isoforms (Chen et al. 2008). (Bottom left) Note that the long isoform contains a pair of IRAlus in its 3' UTR and is preferentially retained in the nucleus. Cytoplasmic and nuclear RNA fractionation of scramble and CARM1 knockdown cells followed by Northern blotting to detect *nicn1* mRNAs. *tRNA<sup>lys</sup>* and *actin* revealed a successful cytoplasmic and nuclear fractionation. Equivalent amounts of RNA from different compartments were loaded as indicated by 28S and 18S rRNAs. (Bottom right) The relative subcellular distribution of the long isoform of *nicn1* mRNA was quantified from the left panels by ImageJ and normalized to the relative amount of nuclear *actin* mRNA from the same stripped membrane. (F) Genes containing IRAlus in 3' UTRs are enriched in the NEAT1-bound active chromatin sites. NEAT1 CHART-seq data in MCF7 cells were retrieved from West et al. (2014). Genes containing IRAlus in 3' UTRs were identified from RefSeq by a home-brewed pipeline. In B, D, and E, error bars represent  $\pm$ SD in triplicate experiments. (\*)  $P < 0.05$ ; (\*\*)  $P < 0.01$ ;  $n = 3$ .

*p54<sup>nrb</sup> methylation by CARM1 regulates nuclear retention of mRNAs containing IRALus*

The next question is whether this CARM1-regulated nuclear retention is dependent on p54<sup>nrb</sup>. To answer this question, we knocked down CARM1 or p54<sup>nrb</sup> and then followed the expression and the subcellular distribution of the IRALus-containing reporter plasmid Flag-mcherry-IRALus. The pair of IRALus used in this construct is from the 3' UTR of the *Nicn1* gene (Chen et al. 2008). While knockdown of CARM1 reduced Flag-mcherry expression (Fig. 3A, lane 2; Supplemental Fig. S7A) with an enhanced nuclear retention of *Flag-mcherry-IRALus* mRNAs (Fig. 3B), as other assays revealed (Fig. 2; Supplemental Figs.

S3, S4), knockdown of p54<sup>nrb</sup> enhanced Flag-mcherry expression (Fig. 3A, lane 4; Supplemental Fig. S7A) with a reduced nuclear retention of *Flag-mcherry-IRALus* mRNAs (Fig. 3B). Double knockdown of CARM1 and p54<sup>nrb</sup> showed little change in both protein expression and mRNA nuclear retention (Fig. 3A [lane 3], B). These results confirm that the nuclear retention of mRNAs with 3' UTR IRALus is mediated by the paraspeckle-localized protein p54<sup>nrb</sup> and that CARM1 suppresses this nuclear retention pathway (Supplemental Fig. S7C).

We next asked whether the catalytic activity of CARM1 is required for the observed nuclear retention. We expressed the wild-type or the catalytically inactive E266Q mutant of CARM1 (Lee et al. 2002) in scramble or

**Figure 3.** IRALus mRNA nuclear retention is achieved through p54<sup>nrb</sup> and requires the catalytic activity of CARM1. (A) IRALus mRNAs nuclear retention is achieved through p54<sup>nrb</sup>. (Top) A schematic drawing of Flag-mcherry-containing IRALus in its 3' UTR (*Flag-mcherry-IRALus*). (Bottom) Knockdown of CARM1 (lane 2) or p54<sup>nrb</sup> (lane 4) or double knockdown of CARM1 and p54<sup>nrb</sup> (lane 3) in HeLa cells expressing Flag-mcherry-IRALus, followed by Western blotting. Note that knockdown of CARM1 suppresses Flag-mcherry expression, while knockdown of p54<sup>nrb</sup> increases Flag-mcherry expression. (B) The altered Flag-mcherry protein expression in A corresponds to altered nuclear retention of transcripts of *Flag-mcherry-IRALus*. The relative subcellular distribution of transcripts of *Flag-mcherry-IRALus* from the same batch of transfected cells as described in A was investigated by RT-qPCR by probing *mcherry*. The level of nuclear retention was presented as the ratio of nuclear-retained transcripts of *Flag-mcherry-IRALus* to those in the cytoplasm after normalization to the relative amount of *actin* mRNA in each fraction. The endogenous mRNA with 3' UTR IRALus was also assayed and normalized in the same way. (C) IRALus mRNA nuclear retention is dependent on the catalytic activity of CARM1. Reintroduction of wild-type (WT) CARM1 or the catalytic inert E266Q-CARM1 into scramble (lanes 2,3) or

CARM1 knockdown (KD) (lanes 5,6) HeLa cells expressing Flag-mcherry-IRALus, followed by Western blotting. Note that expression of wild-type CARM1 but not the E266Q-CARM1 in CARM1 knockdown cells could rescue the suppressed expression of Flag-mcherry-IRALus. (D) Altered Flag-mcherry protein expression in C corresponds to the altered nuclear retention of transcripts of *Flag-mcherry-IRALus*. The relative subcellular distribution of transcripts of *Flag-mcherry-IRALus* and the endogenous mRNA with 3' UTR IRALus from the same batch of transfected cells as described in C were investigated by RT-qPCR. See B for details. (E) Mutation of CARM1 methylation sites on p54<sup>nrb</sup> enhances the p54<sup>nrb</sup>-mediated mRNA nuclear retention. Reintroduction of the lysine replacement of Arg357, Arg365, and Arg378 (R357K, R365K, and R378K) of p54<sup>nrb</sup> (p54<sup>nrb</sup>-MUT; lane 3) into p54<sup>nrb</sup> knockdown cells resulted in an enhanced mCherry suppression compared with that of wild-type p54<sup>nrb</sup> (lane 2), as revealed by Western blotting. (F) Altered Flag-mcherry expression in E corresponds to the altered nuclear retention of transcripts of *Flag-mcherry-IRALus*. The relative subcellular distribution of transcripts of *Flag-mcherry-IRALus* and the endogenous mRNA with 3' UTR IRALus from the same batch of transfected cells as described in E were investigated by RT-qPCR. See for details. In B, D, and F, error bars represent  $\pm$ SD in triplicate experiments. (\*)  $P < 0.05$ ; (\*\*)  $P < 0.01$ ;  $n \geq 3$ .

CARM1 stable knockdown cell lines followed by the reporter assays described above (Fig. 3A,B). We found that reintroduction of the wild-type CARM1, but not the E266Q-CARM1, into CARM1 knockdown cells in which p54<sup>nrb</sup> is largely unmethylated due to CARM1 knockdown could largely restore the reduced Flag-mcherry expression (Fig. 3C, lanes 4–6; Supplemental Fig. S7B), the enhanced nuclear retention of *Flag-mcherry-IRAlus* mRNAs, and the endogenous mRNA with 3' UTR *IRAlus* (Fig. 3D). However, reintroduction of either wild-type or E266Q-CARM1 into scramble treated cells in which CARM1 exists and p54<sup>nrb</sup> is methylated had little effect on the reporter assay or the endogenous mRNA with 3' UTR *IRAlus* (Fig. 3C [lanes 1–3], D).

Moreover, we set up to examine whether the p54<sup>nrb</sup> variant carrying the lysine replacement of Arg357, Arg365, and Arg378 (R357K, 365K, and R378K) that showed a reduced p54<sup>nrb</sup> methylation by CARM1 (Fig. 1C) could enhance the p54<sup>nrb</sup>-mediated mRNA nuclear retention. Reintroduction of the p54<sup>nrb</sup> variant that carries these three point mutants (R357K, 365K, and R378K) into p54<sup>nrb</sup> knockdown cells not only was able to restore the p54<sup>nrb</sup> function but also exhibited a stronger effect on protein expression suppression and the corresponding mRNA nuclear retention in the reporter assay (Fig. 3E,F). Meanwhile, a similar observation was also seen in the examined endogenous mRNA with 3' UTR *IRAlus* (Fig. 3F). Together, these results strongly suggest that CARM1 methylation on p54<sup>nrb</sup> attenuates the p54<sup>nrb</sup>-mediated mRNA nuclear retention.

#### *The absence of CARM1 enhances the association of p54<sup>nrb</sup> and mRNAs with IRAlus*

How does p54<sup>nrb</sup> methylation by CARM1 alter mRNA nuclear retention? Since p54<sup>nrb</sup> can bind to *IRAlus* mRNAs and subsequently retain them in the nucleus (Prasanth et al. 2005; Chen et al. 2008; Mao et al. 2011a), we performed p54<sup>nrb</sup> RNA immunoprecipitation (RIP) assays to examine whether the methylation of p54<sup>nrb</sup> could alter its binding activity with the *IRAlus* mRNAs. Both formaldehyde cross-linking RIP and UV cross-linking RIP with the anti-p54<sup>nrb</sup> antibody in scramble and CARM1 knockdown cell lines revealed that the absence of CARM1 augmented the association of p54<sup>nrb</sup> and mRNAs with *IRAlus* (Fig. 4A,B). Importantly, the lysine replacement of Arg357, Arg365, and Arg378 (R357K, 365K, and R378K) of Flag-p54<sup>nrb</sup> that showed a reduced p54<sup>nrb</sup> methylation by CARM1 (Fig. 1C) also increased its ability to bind to mRNAs with *IRAlus* compared with the wild-type Flag-p54<sup>nrb</sup> (Fig. 4C), with an anti-Flag antibody UV cross-linking RIP in HeLa cells.

To further confirm that p54<sup>nrb</sup> unmethylated in its coiled-coil domain has an increased ability to bind to mRNA-*IRAlus*, we then performed a reciprocal pull-down assay by tagging an aptamer tRSA (Iioka et al. 2011) to *IRAlus* RNA (tRSA-*IRAlus*) (Fig. 4D). Following tRSA immunoprecipitation with nuclear extracts, we found that tRSA-*IRAlus*, but not the tRSA alone, was

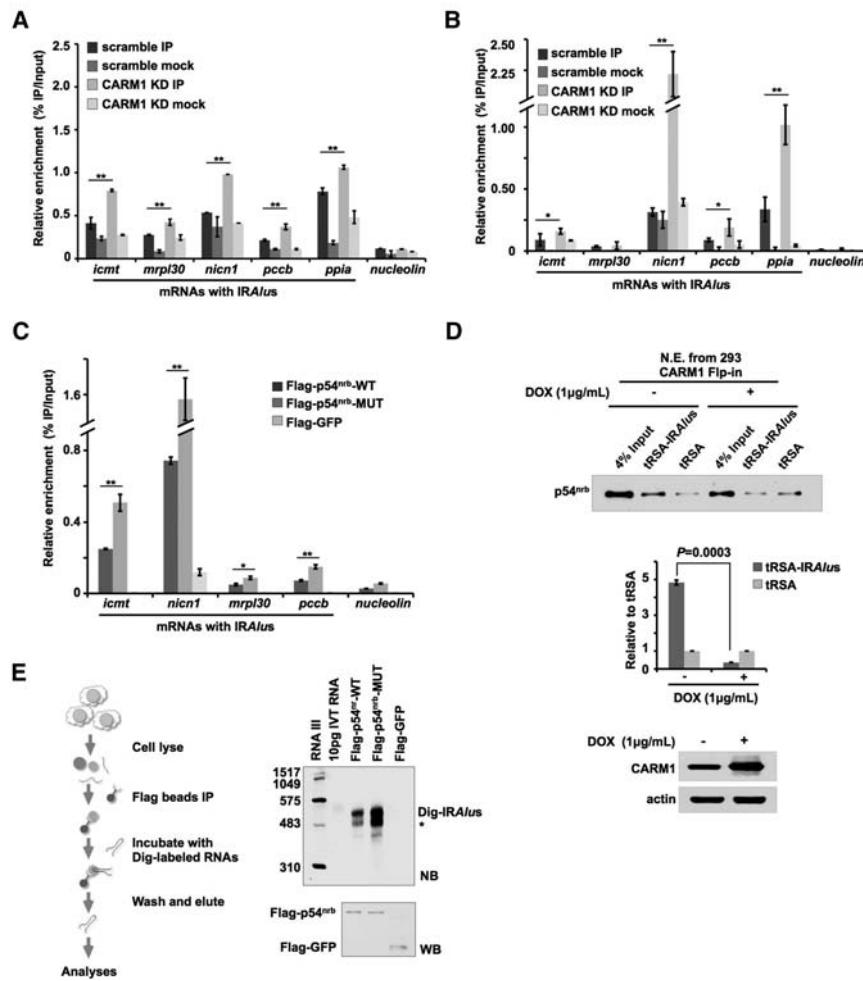

preferentially associated with p54<sup>nrb</sup> (Fig. 4D). Overexpression of CARM1 resulted in reduced binding of tRSA-*IRAlus* with p54<sup>nrb</sup> (Fig. 4D), confirming that methylation by CARM1 on p54<sup>nrb</sup> reduced its ability to bind to RNA-*IRAlus*. Moreover, the partially purified Flag-p54<sup>nrb</sup>-MUT carrying the lysine replacements of R357K, 365K, and R378K significantly increased its ability to bind to the in vitro transcribed *IRAlus* compared with the wild-type protein (Fig. 4E). Since R357 and R365 are located at the coiled-coil domain and R378 is located very close to this domain at the C terminus of p54<sup>nrb</sup> (Supplemental Fig. S2D), these results strongly suggest that methylation on p54<sup>nrb</sup> at or near the coiled-coil domain by CARM1 reduces its capability to associate with RNAs containing *IRAlus*.

#### *p54<sup>nrb</sup> methylation at or near the coiled-coil domain by CARM1 alters its binding to dsRNAs*

How does unmethylated p54<sup>nrb</sup> bind to mRNAs with *IRAlus*? Since p54<sup>nrb</sup> is known to bind to inosine-containing RNAs (Zhang and Carmichael 2001), one possibility is that p54<sup>nrb</sup> binds to edited mRNA-*IRAlus* (Prasanth et al. 2005; Chen et al. 2008). However, some extensively adenosine (A)-to-inosine (I) edited mRNA-*IRAlus* were also exported to the cytoplasm (Prasanth et al. 2005; Chen et al. 2008; Hundley et al. 2008; Elbarbary et al. 2013), and knockdown of ADAR1 did not alter the nuclear retention of these RNAs (Elbarbary et al. 2013), indicating that p54<sup>nrb</sup> can bind to RNAs by recognizing other RNA structures, such as dsRNAs formed by the *IRAlus* at the 3' UTR of mRNAs. We therefore examined whether p54<sup>nrb</sup> could bind to dsRNAs and whether p54<sup>nrb</sup> methylation by CARM1 could selectively alter its binding to these molecules.

The in vitro binding assays revealed that full-length of p54<sup>nrb</sup> bound to both dsRNAs and ssRNAs (Fig. 5A); importantly, knockdown of CARM1 altered the binding ability of p54<sup>nrb</sup> to only dsRNAs but not to ssRNAs (Fig. 5A). With a newly developed antibody (620me) that specifically recognizes the methylated R357 and R365 on a p54<sup>nrb</sup> peptide (Fig. 5B, left panels), we found that the methylated p54<sup>nrb</sup> (620me) was enriched in ssRNA but was barely detected in dsRNA pull-downs (Fig. 5B, right panels). This observation further suggests that CARM1 methylation on p54<sup>nrb</sup> reduces its binding capacity to dsRNAs. Moreover, the partially purified Flag-p54<sup>nrb</sup>-MUT carrying the lysine replacements of R357K, 365K, and R378K promoted its binding capability to the in vitro transcribed dsRNAs but showed little binding alteration to ssRNAs (Fig. 5C). These results thus support the notion that p54<sup>nrb</sup> methylation by CARM1 alters its binding to dsRNAs and that the unmethylated p54<sup>nrb</sup> binds more strongly to dsRNAs.

As it has been reported that p54<sup>nrb</sup> bound to ssDNAs (and RNAs) through its N terminus and to DNA through its C terminus (Yang et al. 1993), we speculated that the coiled-coil domain at the C terminus of p54<sup>nrb</sup> might mediate its binding to dsRNAs, such as mRNAs

(DOX) induction. (Middle) The quantitative analyses of the top panel from three independent experiments was induced upon the DOX treatment, as revealed by Western blotting. (E) Partially purified triple mutations of R357K, R365K, and R378K of p54<sup>nrB</sup> (p54<sup>nrB</sup>-MUT) exhibit increased ability to bind to IRAlus RNAs. (Left) A schematic drawing of the experimental flow. (Right) Flag-p54<sup>nrB</sup>-wt, but not Flag-EGFP, exhibited an ability to bind to Dig-labeled IRAlus RNA, Flag-p54<sup>nrB</sup>-MUT showed an enhanced ability to bind to IRAlus RNA.

containing IRAlus. This is indeed the case. Incubation of ssRNAs or dsRNAs with different Flag-tagged p54<sup>nrB</sup> truncations individually expressed in HeLa cells revealed that the truncation of p54<sup>nrB</sup> containing two RRM domains preferred to bind to ssRNAs, and the truncation of p54<sup>nrB</sup> with the addition of the coiled-coil domain exhibited a much higher capacity to bind to dsRNAs (Fig. 5D,E). Importantly, while the partially purified Flag-tagged p54<sup>nrB</sup> carrying only RRM domains showed little association to the in vitro transcribed IRAlus, the inclusion of the coiled-coiled domain to this truncation significantly increased its ability to bind to IRAlus (Fig. 5F), confirming that the coiled-coil domain of p54<sup>nrB</sup> mediates its binding to dsRNAs, including mRNA-IRAlus. Together, these results strongly suggest that p54<sup>nrB</sup> methylation by CARM1 at or near the coiled-coil domain alters the interaction between dsRNAs and p54<sup>nrB</sup> via the coiled-coil domain.

**Figure 4.** p54<sup>nrB</sup> methylation reduces its ability to bind to IRAlus mRNAs. (A) CARM1 deficiency increases the association of p54<sup>nrB</sup> and the endogenous IRAlus mRNAs. The association between p54<sup>nrB</sup> and mRNAs with IRAlus was assayed by formaldehyde cross-linking RIP from scramble or CARM1 knockdown HeLa cells using anti-p54<sup>nrB</sup> and anti-IgG followed by RT-qPCR. Bar plots represent the fold enrichments of RNAs immunoprecipitated by anti-p54<sup>nrB</sup> or anti-IgG over the same amount of input across different samples, and error bars represent SD in triplicate experiments. *Nucleolin* mRNA was a control that does not bind to p54<sup>nrB</sup>. (B) CARM1 deficiency increases the association of p54<sup>nrB</sup> and endogenous IRAlus mRNAs, as assayed by UV cross-linking RIP from scramble or CARM1 knockdown HeLa cells using anti-p54<sup>nrB</sup> and anti-IgG followed by RT-qPCR. See A for details. (C) Lysine replacement of Arg357, Arg365, and Arg378 (R357K, R365K, and R378K) of p54<sup>nrB</sup> (p54<sup>nrB</sup>-MUT) increases the association of p54<sup>nrB</sup> and endogenous IRAlus mRNAs. The interaction of p54<sup>nrB</sup> and endogenous IRAlus mRNAs was assayed by RIP in HeLa cells expressing Flag-p54<sup>nrB</sup>, Flag-p54<sup>nrB</sup>-MUT, or Flag-EGFP followed by RT-qPCR. See A for details. (D) CARM1 overexpression attenuates the interaction between p54<sup>nrB</sup> and IRAlus RNA. (Top) tRSA-RNA pull-downs (Iioka et al. 2011) using in vitro transcribed tRSA-tagged IRAlus RNAs were performed in nuclear extracts of 293 CARM1 Flp-in cells with or without 1  $\mu$ g/mL doxycycline

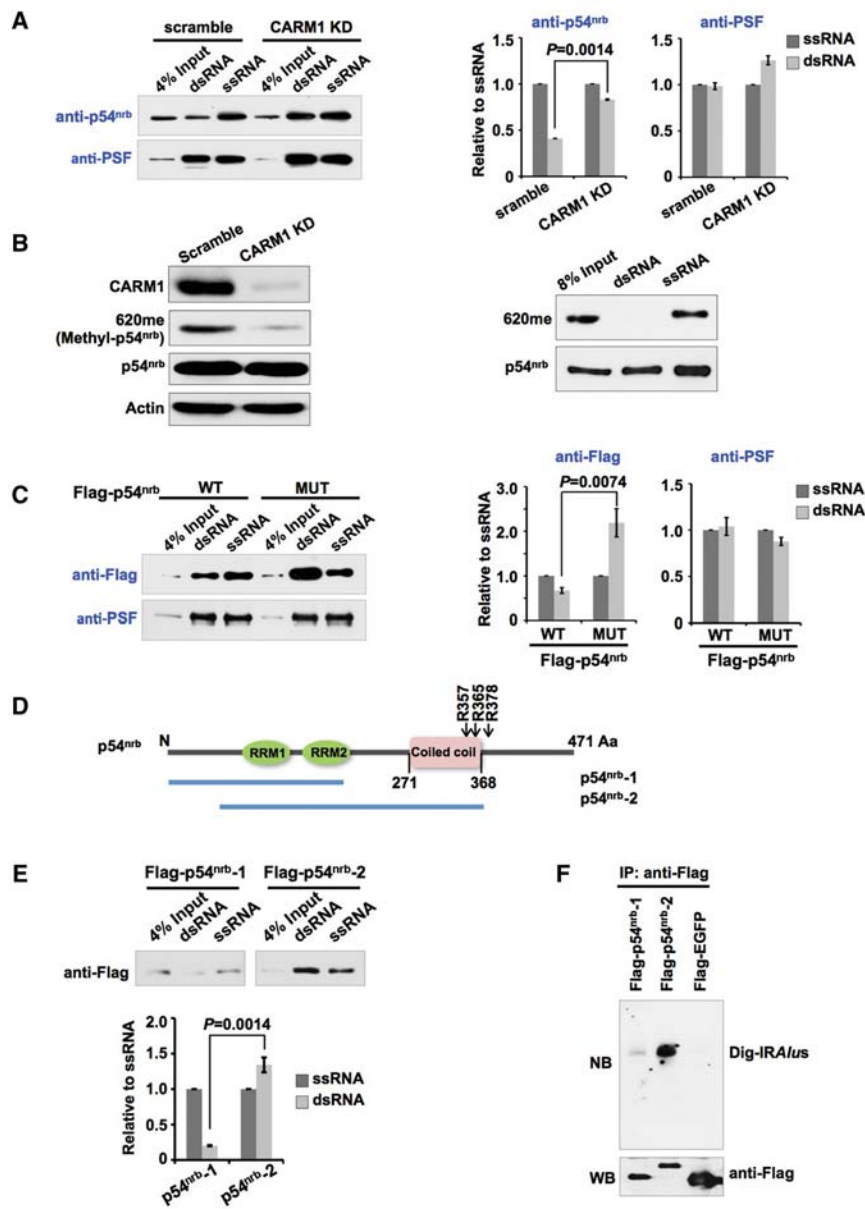

#### CARM1 inhibits NEAT1 transcription and reduces paraspeckle formation

We showed that CARM1 methylated the coiled-coil domain of p54<sup>nrB</sup>, resulting in the reduced binding of p54<sup>nrB</sup> to mRNAs containing IRAlus. CARM1 is also known for its activity in transcription regulation (Chen et al. 1999). CARM1 largely functions as a transcriptional coactivator (Chen et al. 1999) but also acts as a transcriptional cosuppressor (Xu et al. 2001). We then asked whether the paraspeckle-localized CARM1 could also affect *NEAT1* transcription.

Surprisingly, we found that in CARM1 knockdown stable cell lines, the expression of both isoforms of *NEAT1* was increased (Fig. 6A). Correspondingly, the number of paraspeckles was also modestly increased in both CARM1 stable knockdown HeLa cells (Fig. 6B) and HEK293 cells (Fig. 6C). CARM1 chromatin

Hu et al.

Different p54<sup>nrB</sup> truncations shown in *D* were purified and incubated with Dig-labeled *IRAlus* RNAs. See Figure 4E for details. In *A*, *C*, and *E*, error bars represent  $\pm$ SD in triplicate experiments. *P*-values from one-tailed *t*-test in the pairwise comparison are shown.

immunoprecipitation (ChIP) revealed that CARM1 was enriched at the promoter of the *NEAT1* gene (Fig. 6D). Further studies by nuclear run-on (NRO) assays showed that the transcription of nascent transcripts of *NEAT1* was increased upon CARM1 knockdown, confirming the notion that CARM1 could regulate *NEAT1* transcription as a transcriptional cosuppressor.

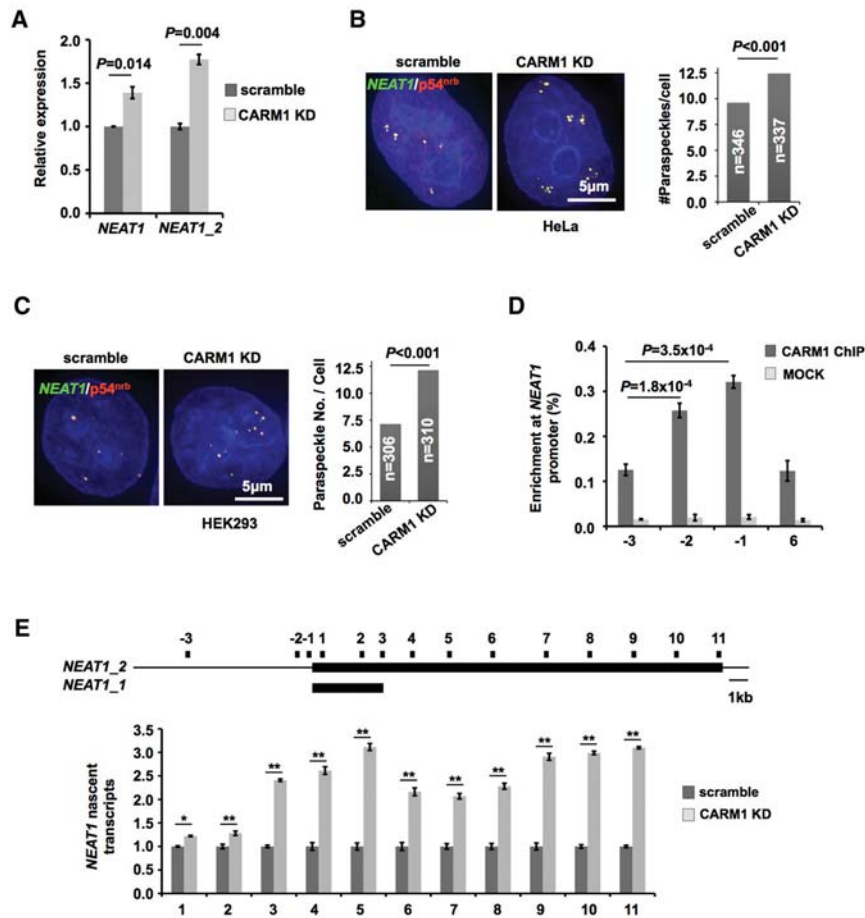

Collectively, we propose a model for CARM1-regulated nuclear retention of mRNAs containing *IRAlus* at paraspeckles. p54<sup>nrB</sup> methylation by CARM1 at the coiled-coil domain reduces its ability to bind to mRNAs containing *IRAlus* (Figs. 2–5). This is in coordination with the transcriptional suppression of CARM1 at the *NEAT1* pro-

Figure 5. p54<sup>nrB</sup> methylation by CARM1 alters its binding to dsRNAs. (*A*) CARM1 knockdown affects p54<sup>nrB</sup> binding to dsRNAs but has little effect on ssRNAs. Biotin-labeled dsRNAs (double-stranded-*egfp* 76–495) or ssRNAs (single-stranded-*egfp* 1–798) were made from in vitro transcription (IVT). Nuclear extracts of scramble or CARM1 knockdown (KD) HeLa cells were incubated with biotin-dsRNA or biotin-ssRNA followed by anti-biotin pull-down and Western blotting with antibodies for anti-p54<sup>nrB</sup> and anti-PSF. (*Right*) The quantitative analyses of the *left* panels from three independent experiments. (*B*) Methylated p54<sup>nrB</sup> binds to few dsRNAs. (*Left*) The 620me antibody was developed to specifically recognize the methylated p54<sup>nrB</sup>. Western blotting analyzed the specificity of 620me antibody purified from rabbit serum immunized with methylated peptides of R357 and R365. p54<sup>nrB</sup> and Actin antibodies were used as controls. (*Right*) The methylated p54<sup>nrB</sup> (620me) was enriched by biotin-ssRNA but not by biotin-dsRNA pull-downs from wild-type HeLa cell nuclear extracts. See *A* for details. (*C*) Lysine replacement of Arg357, Arg365, and Arg378 (R357K, 365K, and R378K) of p54<sup>nrB</sup> (p54<sup>nrB</sup>-MUT) increases the association of p54<sup>nrB</sup> and dsRNAs. (*Right*) The quantitative analyses of the *left* panels from three independent experiments. See *A* for details. (*D*) A schematic drawing of different truncations of p54<sup>nrB</sup> used in *E* and *F*. (*E*) A different domain of p54<sup>nrB</sup> selectively binds to ssRNAs or dsRNAs. (*Top*) Nuclear extracts of HeLa cells transfected with different p54<sup>nrB</sup> truncations were incubated with biotin-dsRNAs or biotin-ssRNAs followed by anti-biotin pull-down and Western blotting with anti-Flag. motor (Fig. 6). Thus, CARM1 can synergistically act at two levels within paraspeckles to regulate its function for mRNA nuclear retention (Fig. 7I).

#### *CARM1 is involved in the poly(I:C)-stimulated enhancement of nuclear retention regulation*

Finally, it will be of interest to identify conditions that affect CARM1-regulated mRNA nuclear retention within paraspeckles. It is known that the transcription of *NEAT1* RNAs and the formation of paraspeckles are induced upon virus infection or poly(I:C) treatment (Saha et al. 2006; Zhang et al. 2013a; Imamura et al. 2014). We therefore

**Figure 6.** CARM1 is enriched at the *NEAT1* promoter and inhibits *NEAT1* transcription and paraspeckle formation. (A) CARM1 deficiency promotes the expression of both isoforms of *NEAT1*. (B) CARM1 knockdown increases paraspeckle formation. (Left) Colocalization of *NEAT1* RNA (green) and p54<sup>nrB</sup> protein (red) revealed paraspeckles in scramble and CARM1 knockdown (KD) HeLa cells. (Right) Statistical analysis of numbers of paraspeckles from >300 cells in scramble and CARM1 knockdown HeLa cells. The *P*-value from a one-tailed *t*-test in the pairwise comparison is shown. (C) CARM1 knockdown increases paraspeckle formation in HEK293 cells. (D) CARM1 is enriched on the promoter region of *NEAT1*. CARM1 ChIP followed by qPCR analyzed the occupation of CARM1 on the *NEAT1* gene. The positions of examined primers are shown in *E*. (E) CARM1 deficiency promotes the transcription of nascent *NEAT1*. (Top) A schematic drawing indicates the primer sets used. (Bottom) A crude preparation of nuclei was subjected to NRO assays under the indicated conditions in HeLa cells. Nascent transcription of *NEAT1* detected from scramble nuclei was defined as one. In A, D, and E, error bars represent  $\pm$ SD in triplicate experiments. (\*) *P* < 0.05; (\*\*) *P* < 0.01; *n*  $\geq$  3.

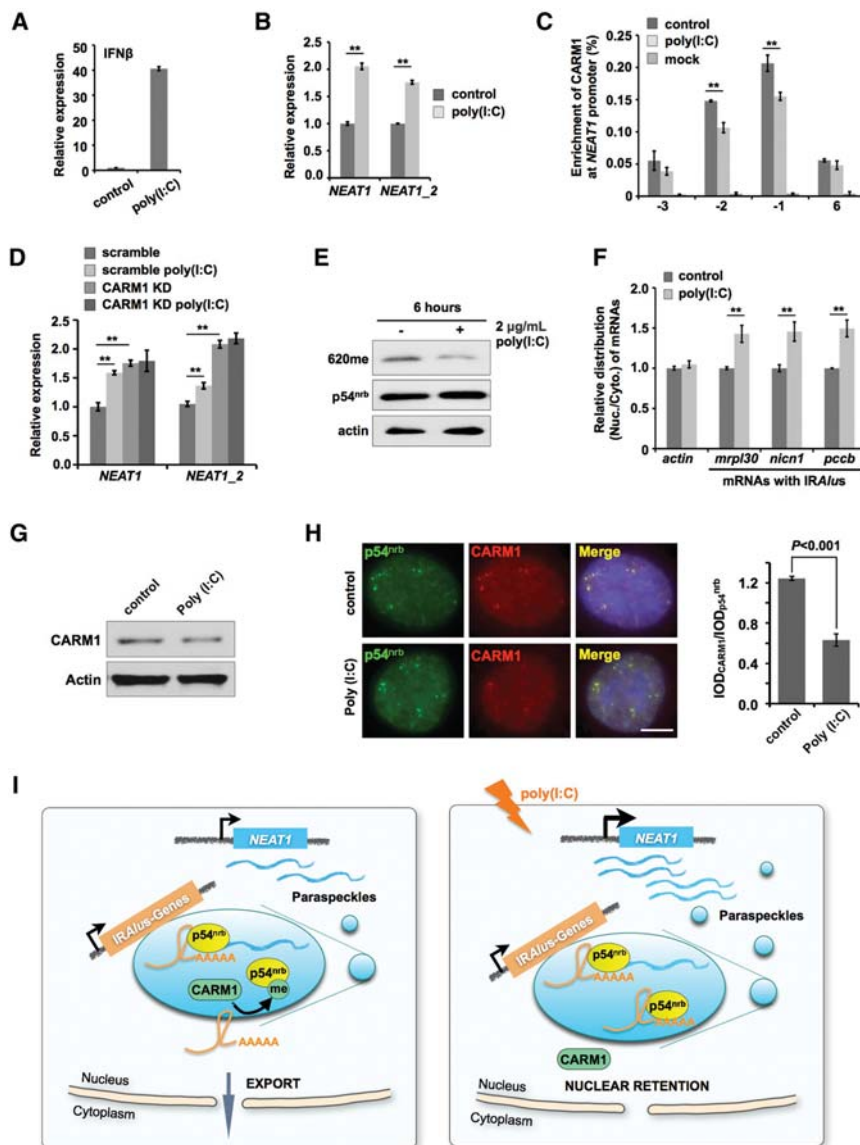

investigated whether CARM1-regulated nuclear retention is affected by poly(I:C) treatment. In our experiments, transfection of poly(I:C) led to increased expression of *interferon  $\beta$*  and *NEAT1* RNAs (Fig. 7A,B). Importantly, we found that the enrichment of CARM1 at the *NEAT1* promoter was reduced upon poly(I:C) treatment (Fig. 7C), corresponding to the observed up-regulation of *NEAT1* RNAs (Fig. 7B). Furthermore, the expression of *NEAT1* RNAs remained at high levels in CARM1 knockdown cells, and *NEAT1* expression could not be further induced upon poly(I:C) treatment (Fig. 7D). In addition, we found that the treatment of cells with poly(I:C) led to a strong reduction of p54<sup>nrB</sup> methylation on these arginine residues (Fig. 7E), while the expression of p54<sup>nrB</sup> remained unchanged. Finally, poly(I:C) treatment also resulted in an enhanced nuclear retention of a number of examined mRNAs containing *IRAlus* (Fig. 7F). Interestingly, we found that upon poly(I:C) treatment, the expression of CARM1 protein remained largely unchanged (Fig. 7G), while the paraspeckle-localized CARM1 was significantly reduced (Fig. 7H), indicating that CARM1 may rapidly change its subcellular localization with an unknown mechanism upon the stress treatment. Taken together, these results suggest that actions of CARM1 at p54<sup>nrB</sup> methylation and *NEAT1* transcription synergistically work together to regulate the

export of transcripts containing *IRAlus* from paraspeckles under certain cellular stresses, such as the poly(I:C) treatment (Fig. 7I).

## Discussion

Paraspeckles play a role in gene regulation through nuclear retention mediated by the association of their key protein component, p54<sup>nrB</sup>, with mRNAs containing inverted repeats (*Alu* repeats in humans) in their 3' UTRs (Prasanth et al. 2005; Chen et al. 2008; Chen and Carmichael 2009; Mao et al. 2011a). Such nuclear-retained mRNAs are inefficiently exported to the cytoplasm, resulting in silencing of gene expression. However, the level of nuclear retention of transcripts containing *IRAlus* is variable, with some such mRNAs located in the nucleus, while others are in the cytoplasm (Prasanth et al. 2005; Chen et al. 2008; Hundley et al. 2008; Chen and Carmichael 2009; Elbarbary et al. 2013). How the nuclear retention of mRNAs containing *IRAlus* at paraspeckles is regulated has remained elusive. Here we demonstrate that CARM1 is a novel component of paraspeckles (Fig. 1). Disruption of CARM1 significantly enhances the nuclear retention of mRNAs containing 3' UTR *IRAlus* and represses gene expression (Fig. 2; Supplemental Figs. S3, S4, S6).

Hu et al.

**Figure 7.** CARM1 is involved in the poly(I:C)-stimulated enhancement of nuclear retention. (A) Poly(I:C) treatment induces the expression of IFN $\beta$ . HeLa cells were transfected with 2  $\mu$ g/mL poly(I:C) for 6 h and then harvested for analysis. (B) Poly(I:C) treatment induces *NEAT1* expression. (C) Poly(I:C) treatment reduces the occupancy of CARM1 at the *NEAT1* promoter. HeLa cells were transfected with poly(I:C) for 6 h and then harvested for CARM1 ChIP followed by qPCR. Data are presented as the percentage of CARM1 coprecipitating DNAs along the *NEAT1* gene versus input under each indicated condition. (D) Poly(I:C) treatment induces *NEAT1* expression in scramble-treated HeLa cells but not in CARM1 knockdown (KD) HeLa cells. (E) Poly(I:C) treatment reduces p54<sup>nrB</sup> methylation. HeLa cells were transfected with 2  $\mu$ g/mL poly(I:C) for 6 h and then harvested for Western blotting analyses. (F) Poly(I:C) treatment enhances the nuclear retention of mRNAs containing *IRAlus*. HeLa cells were transfected with poly(I:C) for 6 h and then harvested for the nuclear and cytoplasmic fractionations. The relative subcellular distribution of transcripts of endogenous transcripts with *IRAlus* was investigated by RT-qPCR, normalized to the relative amount of *actin* mRNA in each fractionation, and compared with control HeLa cells. (G) The expression of CARM1 remains unchanged upon poly(I:C) treatment, as revealed by Western blotting. (H) The poly(I:C) treatment attenuates CARM1 localization to paraspeckles. (Left) Control and poly(I:C) transfected HeLa cells were stained with anti-p54<sup>nrB</sup> and anti-CARM1 antibodies, and representative images are shown. (Right) The statistics of p54<sup>nrB</sup> and CARM1 colocalization. The IODs (integrated optical densities) of punctuated anti-CARM1 and anti-p54<sup>nrB</sup> signals were

measured by Image-Pro Plus from images taken with the same parameters ( $n > 100$  double-positive staining cells). The ratio of  $\text{IOD}_{\text{CARM1}}/\text{IOD}_{\text{p54}^{\text{nrB}}}$  was used to evaluate the extent of colocalization. The  $P$ -value from a one-tailed  $t$ -test in the pairwise comparison is shown. (I) A model of how the nuclear retention of *IRAlus* mRNAs at paraspeckles is regulated. (Left) Under normal conditions, CARM1 suppresses *NEAT1* transcription and paraspeckle formation and also methylates p54<sup>nrB</sup>, resulting in the reduced ability to bind to mRNAs containing *IRAlus*. (Right) Upon appropriate stimulation, such as upon poly(I:C) treatment, actions of CARM1 are attenuated, resulting in an increased expression of *NEAT1* RNA, unmethylated p54<sup>nrB</sup>, and enhanced nuclear retention of *IRAlus* mRNAs at paraspeckles. See the text for details. In B–D and F, error bars represent  $\pm$ SD in triplicate experiments. (\*\*)  $P < 0.01$ ;  $n = 3$ .

To achieve this regulation, CARM1 methylates p54<sup>nrB</sup> (Fig. 1; Supplemental Figs. S1, S2) and reduces its ability to associate with dsRNAs, such as mRNAs with *IRAlus* (Figs. 4, 5). On the other hand, CARM1 suppresses *NEAT1* transcription and inhibits paraspeckle formation (Fig. 6).

While p54<sup>nrB</sup> is required for nuclear retention of mRNAs with 3' UTR *IRAlus*, the catalytic activity of CARM1 is also required for this effect (Fig. 3). How is binding of p54<sup>nrB</sup> to mRNA-*IRAlus* achieved? Since it is known that p54<sup>nrB</sup> binds to inosine-containing RNAs

(Zhang and Carmichael 2001) and that a strong correlation between A-to-I RNA editing and retention was seen in mRNAs containing inverted repeats (Prasanth et al. 2005; Chen and Carmichael 2008; Chen et al. 2008), it has been thought that one of the consequences of *Alu* RNA editing is to retain edited mRNAs within nuclear paraspeckles. However, some mRNAs with edited *IRAlus* in their 3' UTRs were also observed in the cytoplasm (Chen et al. 2008; Hundley et al. 2008). Knockdown of ADARI, which is responsible for A-to-I RNA editing, has little effect on the export of nuclear-retained *IRAlus*

mRNAs (Elbarbary et al. 2013). These results thus suggested that another nuclear retention signal is required for p54<sup>nrb</sup>-mediated mRNA nuclear retention in addition to RNA editing. Another formal possibility is that long imperfect duplexes formed by *IRAlus* in the 3' UTRs of genes might influence gene regulation even in the absence of editing. We showed that such unique hairpin structures can directly bind to unmethylated p54<sup>nrb</sup> (Figs. 4, 5), which in turn could lead to the nuclear retention of mRNAs containing *IRAlus* within paraspeckles. Moreover, it has been reported that p54<sup>nrb</sup> can bind DNA through its C terminus (Yang et al. 1993). Consistent with this view, we demonstrated that the selective binding of dsRNAs to p54<sup>nrb</sup> also requires its coiled-coil domain (Fig. 5).

Post-translational modifications of proteins play key roles in the regulation of many cellular processes by altering their associated effectors, including both proteins and a few reported RNAs. For instance, methylation/demethylation of Polycomb 2 protein could modulate its interaction with different lncRNAs (either TUG1 or MALAT1) with an unknown mechanism, resulting in the coordinated gene expression program in distinct subnuclear architectural compartments in response to growth signals (Yang et al. 2011). We observed that CARM1 methylation on p54<sup>nrb</sup> occurs at or near the dsRNA-binding coiled-coil domain and that knockdown of CARM1 significantly alters p54<sup>nrb</sup>-binding activity to dsRNAs but not ssRNAs (Fig. 5), resulting in enhanced nucleocytoplasmic export of mRNAs containing inverted *Alu* repeats. Thus, this regulation pathway represents one of a few examples where post-translational modification of an RNA-binding protein affects protein–RNA interaction and gene expression. Furthermore, although our data support the view that the reduced binding capability of methylated p54<sup>nrb</sup> to dsRNAs could result from a direct conformational change of p54<sup>nrb</sup> methylation at the coiled-coil domain, we cannot exclude the possibility that these methyl sites may recruit other effector proteins to facilitate the release of mRNA-*IRAlus* from methylated p54<sup>nrb</sup> (Yang et al. 2014). Finally, the dsRNA-binding protein STAU1 (Wickham et al. 1999) was recently shown to compete with p54<sup>nrb</sup> for the binding of 3' UTR *IRAlus*, independent of editing (Elbarbary et al. 2013). It will be of interest to examine whether the binding of 3' UTR *IRAlus* with STAU1 occurs after the release of mRNAs containing *IRAlus* from methylated p54<sup>nrb</sup>.

Although many lncRNAs have been implicated in gene regulation and mammalian development (Ulitsky and Bartel 2013), how the expression of lncRNAs is regulated has remained poorly understood. Interestingly, we found that paraspeckle-localized CARM1 also plays a role in the transcription regulation of *NEAT1* RNAs and affects paraspeckle formation (Fig. 6). CARM1 is recognized as a transcriptional coactivator (Chen et al. 1999; Bedford and Clarke 2009) but also acts as a transcriptional cosuppressor, such as in the cyclic adenosine monophosphate signaling pathway (Xu et al. 2001). In the case of *NEAT1* regulation, we found that CARM1 is enriched at the *NEAT1* promoter and acts as a transcriptional repressor

(Fig. 6). Conspicuously, this “negative” regulation of *NEAT1* transcription and paraspeckle formation by CARM1 could in fact lead to a “positive” gene expression output by allowing the export of more mRNAs with *IRAlus* to the cytoplasm for protein translation. This final output in gene expression is therefore consistent with a general role of CARM1 in promoting gene transcription (Chen et al. 1999; Bedford and Clarke 2009). However, we do not yet know what directs CARM1 to the *NEAT1* promoter and what other factors are involved in this *NEAT1* transcription regulation by CARM1. It had been reported recently that *NEAT1* RNAs can sequester the transcriptional regulator PSF to regulate gene expression (Hirose et al. 2014; Imamura et al. 2014). Since PSF is largely localized to paraspeckles, it will be of interest to examine whether PSF can autoregulate *NEAT1* transcription in coordination with CARM1.

The identification of CARM1 functioning at two levels within paraspeckles is particularly interesting. On the one hand, CARM1 methylates p54<sup>nrb</sup>, resulting in the reduced ability to binding to mRNAs containing *IRAlus* (Figs. 3–5). On the other hand, CARM1 suppresses *NEAT1* transcription and paraspeckle formation (Figs. 6, 7I). Actions of CARM1 at these two levels synergistically work together to regulate the export of transcripts containing *IRAlus* from paraspeckles. In response to certain cellular stressors, such as poly(I:C) treatment, we observed the reduced p54<sup>nrb</sup> methylation (enhanced mRNA nuclear retention) and the decreased binding of CARM1 to the *NEAT1* promoter (enhanced transcription of *NEAT1* and paraspeckle formation) (Fig. 7A–F). Thus, this paraspeckle-mediated nuclear retention was enhanced upon poly(I:C) stimulation, leading to less translation of mRNAs containing *IRAlus* (Fig. 7I).

## Materials and methods

### *Cell culture, plasmids, transfection, and knockdown with shRNAs*

HeLa, HEK293, and MEF cell lines were cultured using standard protocols. HEK293 CARM1 Flp-in stable cell line, wide-type, and CARM1<sup>-/-</sup> MEFs have been described (Cheng et al. 2007). Transfection was carried out with either X-tremeGENE 9 (Roche) or Lipofectamine 2000 (Invitrogen) according to the manufacturers' protocols. To generate Flag-p54<sup>nrb</sup>-wt (MUT) or Flag-EGFP stable cell lines, pcDNA3.1 (+)-Flag-p54<sup>nrb</sup>-wt (MUT) or pcDNA3.1 (+)-Flag-EGFP was transfected into HEK293 CARM1 Flp-in cells followed by G418 selection. The plasmids pEGFP-SC-Nicn1-*Alu* (*IRAlus*) and pEGFP-SC-Lin28-*Alu* (*IRAlus*) have been described (Chen et al. 2008). CARM1 knockdown was carried out as described (Ou et al. 2011), and stable HeLa and HEK293 lines were generated. To knock down p54<sup>nrb</sup>, the sequence “GCAGG CGAAGTCTTCATTCAT” was inserted into pLVTHM vector with MluI and ClaI, and the construct was packaged into lentivirus to infect HeLa cells. All plasmids used are listed in the Supplemental Material.

### *In vitro methylation assay*

In vitro methylation assay was carried out as described (Cheng et al. 2007). GST-CARM1 and His-p54<sup>nrb</sup> were overexpressed

and purified from *E. coli*. In vitro methylation reactions were performed in a final volume of 30  $\mu$ L of PBS (pH 7.4). The reaction contained 0.5–1.0  $\mu$ g of substrates and 0.2–0.4  $\mu$ g of recombinant enzymes. All methylation reactions were carried out in the presence of 0.5  $\mu$ Ci S-adenosyl-L-[methyl-<sup>3</sup>H] methionine (85 Ci/mmol from a 0.5 mCi/mL stock solution; Perkin-Elmer). The reaction was incubated for 1 h at 30°C and then subjected to fluorography by separation on SDS-PAGE (12% gel), transferred to a PVDF membrane, treated with Enhance (Perkin-Elmer), and exposed to film overnight. After in vitro methylation followed by fluorography, the same membrane was subjected to Coomassie blue staining, immunoblotting with anti-His tag, or Ponceau staining. We overlaid the fluorograph with the stained membrane and signals from immunoblots and verified that the stained protein bands matched with the methylated bands.

#### Immunoprecipitation

HeLa cells ( $10^7$ ) were harvested and suspended in immunoprecipitation buffer (50 mM HEPES at pH 7.6, 250 mM NaCl, 5 mM EDTA at pH 8.0, 0.1% NP-40, 1 mM PMSF, protease inhibitor cocktail) followed by sonication. After centrifuging at 13,000 rpm for 15 min at 4°C, the supernatant was transferred into a new tube and precleared with 10  $\mu$ L of Dynabeads G. Next, the precleared supernatant was incubated with 20  $\mu$ L of Dynabeads G with antibodies for p54<sup>nrb</sup> (BD) or IgG (Sigma) for 4 h at 4°C followed by washing with immunoprecipitation buffer. To harvest the protein complex, 50  $\mu$ L of 1 $\times$  SDS loading buffer (62.4 mM Tris at pH 6.8, 10% glycerol, 2% SDS, 0.0012% bromophenol blue) was added, incubated for 10 min at 95°C, and analyzed by Western blotting.

#### MS for methylation

pcDNA3.1 (+)-Flag- p54<sup>nrb</sup> was transfected into scramble and CARM1 knockdown stable HeLa cells for 24 h, and cells transfected with Flag-EGFP were used as control. Cells ( $10^7$ ) were harvested as described above, and 20  $\mu$ L of anti-Flag M2 beads (Sigma) was used in each reaction. One out of 10 immunoprecipitated beads was saved for Western blotting and silver staining, and the others were used for MS. Beads were washed with PBS and then aliquoted into three parts (one each for Glu-C, substilisin, and trypsin digestion) followed by incubation with DTT and urea for 30 min at 60°C. Next, 15 mM iodoacetamide was added into the beads and incubated for 20 min at room temperature. Digestion was performed using sequencing grade Glu-C, substilisin, and trypsin for 4 h at 37°C. Liquid chromatography-tandem MS (LC-MS/MS) was carried out on the Thermo Q Exactive Hybrid quadrupole orbitrap mass spectrometer.

#### Nuclear and cytoplasmic RNA fractionation, RNA isolation, qRT-PCR, and Northern blotting

Nuclear and cytoplasmic fractionation was carried out as described (Chen et al. 2008) with slight modifications. Cell pellets were suspended by gentle pipetting in 200  $\mu$ L of lysis buffer (10 mM Tris at pH 8.0, 140 mM NaCl, 1.5 mM MgCl<sub>2</sub>, 0.5% Igepal, 2 mM vanadyl ribonucleoside complex [VRC]) and incubated for 5 min on ice. One-fifth of the lysate was saved as total RNA. The rest of the lysate was centrifuged at 1000g for 3 min at 4°C to pellet the nuclei, and the supernatant was the cytoplasmic fraction. To obtain pure cytoplasmic RNA, the supernatant fraction was further centrifuged at 13,000 rpm for 10 min at 4°C and then collected carefully to a new tube, and RNA was extracted with Trizol. To obtain pure nuclear RNA, the nuclear pellets

were subjected to two additional washes with 160  $\mu$ L of lysis buffer and one additional wash by adding 0.5% deoxycholic acid into the lysis buffer. Finally, the purified nuclei were resuspended in 100  $\mu$ L of lysis buffer followed by extraction with Trizol. The RNA was extracted per standard protocols. For Northern blotting, equal amounts of RNAs from different fractionations were loaded. Northern blotting was performed using the DIG Northern starter kit (Roche). The probes used were produced by digoxigenin (Dig)-labeled in vitro transcription (IVT) of specific PCR products. Primers used for amplifying templates for IVT are listed in the Supplemental Material. For qRT-PCR, after treatment with DNase I (Ambion), equal amounts of RNAs from different fractionations were reverse-transcribed into cDNAs with SuperScript II (Invitrogen).  $\beta$ -Actin was used as an endogenous control.

#### RNA ISH and immunofluorescence microscopy

Simultaneous RNA ISH and immunofluorescence were performed as described (Yin et al. 2012) with slight modifications. Hybridization was performed with in vitro transcribed Dig-labeled probes. For colocalization studies, cells were costained with mouse anti-p54<sup>nrb</sup> (BD) and/or rabbit anti-CARM1 (Bethyl Laboratories). The nuclei were counterstained with DAPI. Images were taken with a Zeiss LSM 510 microscope or an Olympus IX70 DeltaVision RT deconvolution system microscope. For statistical analysis, >300 cells from each group were observed and calculated. Image analyses of signal intensity were carried out by Image-Pro Plus according to standard protocols and were described previously (Yin et al. 2015).

#### Formaldehyde cross-linking RIP

HeLa cells ( $10^7$ ) were washed twice with 5 mL of PBS and cross-linked with 1% formaldehyde for 10 min at room temperature. Cross-linking was stopped by the addition of glycine to a final concentration of 0.25 M followed by incubation for 5 min at room temperature. After washing twice with 5 mL of cold PBS, cells were collected and suspended in 1 mL of RIP buffer (50 mM Tris-HCl at pH 7.5, 150 mM NaCl, 1% NP40, 0.5% sodium deoxycholate, 1 mM PMSF, 2 mM VRC, protease inhibitor cocktail). The cells were homogenized by sonication and then centrifuged at 13,000 rpm for 10 min at 4°C to remove the insoluble material. Fifty microliters of supernatant was saved as input. The rest of the supernatant was precleared by applying 10  $\mu$ L of Dynabeads G (Invitrogen) with 20  $\mu$ g/mL yeast tRNA for 1 h at 4°C. Next, the precleared lysate was incubated with Dynabeads G that were precoated with 2  $\mu$ g of antibodies for p54<sup>nrb</sup> (BD) or IgG (Sigma) for 4 h at 4°C. The beads were washed three times for 5 min with washing buffer I (50 mM Tris-HCl at pH 7.5, 1 M NaCl, 1% NP40, 1% sodium deoxycholate, 2 mM VRC) and three times for 5 min with washing buffer II (50 mM Tris-HCl at pH 7.5, 1 M NaCl, 1% NP40, 1% sodium deoxycholate, 2 mM VRC, 1 M urea). The immunoprecipitated complex was eluted from Dynabeads G by adding 100  $\mu$ L of elution buffer (100 mM Tris HCl at pH 8.0, 10 mM EDTA, 1% SDS). Proteinase K (0.2  $\mu$ g/ $\mu$ L) and 200 mM NaCl were added into the RNA sample and incubated for 1 h at 42°C followed by 1 h at 65°C. RNA was then extracted, digested with DNase I (Ambion), and used to synthesize cDNA using random hexamers (SuperScript III, Invitrogen) followed by qPCR analysis (AceQ, Vazyme).

#### UV cross-linking RIP

UV cross-linking RIP was carried out as described (Zhang et al. 2013b). HeLa cells ( $10^7$ ) were washed twice with 5 mL of cold

PBS and irradiated at 150 mJ/cm<sup>2</sup> at 254 nm in a Stratalinker. Cells were collected and resuspended in 1 mL of RIP buffer. The cells were homogenized by sonication and then centrifuged at 13,000 rpm for 10 min at 4°C to remove the insoluble material. Fifty microliters of supernatant was saved as input. The rest of the supernatant was precleared by applying 10 µL of Dynabeads G (Invitrogen) with 20 µg/mL yeast tRNA for 1 h at 4°C. Next, the precleared lysate was incubated with Dynabeads G that were pre-coated with 2 µg of antibodies for p54<sup>nrb</sup> (BD) or IgG (Sigma) for 4 h at 4°C. The beads were washed three times for 5 min with washing buffer I and three times for 5 min with washing buffer II. The immunoprecipitated complex was eluted from Dynabeads G by adding 100 µL of elution buffer (100 mM Tris-HCl at pH 7.0, 5 mM EDTA, 10 mM DTT, 1% SDS). Five microliters of 10 mg/mL proteinase K was added into the RNA sample and incubated for 30 min at 55°C. RNA was then extracted, digested with DNase I (Ambion), and used to synthesize cDNA using random hexamers (SuperScript III, Invitrogen) followed by qPCR analysis.

### ChIP

ChIP was carried out as described (Zhang et al. 2013b). HeLa cells (10<sup>7</sup>) were cross-linked in 1% formaldehyde for 5 min at room temperature, quenched by adding 0.25 M glycine, and then collected by cell scraper. After being suspended in 1 mL of ChIP lysis buffer (1% Triton X-100, 0.1% sodium deoxycholate, 50 mM Tris at pH 8.0, 150 mM NaCl, 5 mM EDTA), cells were sonicated until the majority of DNA fragments was 300–500 base pairs (bp). Supernatants were collected and subjected to pre-clearing with Dynabeads G (Invitrogen) with a supplement of 100 µg of ssDNA. Next, the precleared lysates were used for ChIP with 2 µg of CARM1 antibody (Bethyl Laboratories). ChIP was carried out overnight at 4°C. The beads were washed with 600 µL of ChIP lysis buffer, 600 µL of high-salt wash buffer (1% Triton X-100, 0.1% deoxycholate, 50 mM Tris at pH 8.0, 500 mM NaCl, 5 mM EDTA), and 600 µL of LiCl immune complex wash buffer (0.25 M LiCl, 0.5% Igepal, 0.5% deoxycholate, 10 mM Tris at pH 8.0, 1 mM EDTA) sequentially followed by two washes with 600 µL of 1× TE buffer (10 mM Tris at pH 8.0, 1 mM EDTA) at 4°C. The immunoprecipitated complex was eluted from Dynabeads G by adding 200 µL of fresh-prepared elution buffer (1% SDS, 0.1 M NaHCO<sub>3</sub>) with rotation for 15 min at room temperature. Next, the reverse cross-linking was carried out by adding 8 µL of 5 M NaCl and incubation for 4 h at 65°C followed by the addition of 4 µL of 0.5 M EDTA and 10 µL of 10 mg/mL proteinase K for 2 h at 55°C. DNA was then extracted and analyzed by qPCR.

### NRO assay

The NRO in HeLa cells was performed as described (Zhang et al. 2013b). HeLa cells (10<sup>7</sup>) were washed with cold PBS three times and incubated in swelling buffer (10 mM Tris at pH 7.5, 2 mM MgCl<sub>2</sub>, 3 mM CaCl<sub>2</sub>) for 5 min on ice. Cells were collected, suspended in 1.5 mL of lysis buffer (10 mM Tris at pH 7.5, 2 mM MgCl<sub>2</sub>, 3 mM CaCl<sub>2</sub>, 0.5% Igepal, 10% glycerol, 2 U/mL RNasin ribonuclease inhibitor [Promega]), gently pipetted, and then centrifuged at 1500g for 10 min at 4°C. The pellets were collected and subjected to another lysis to obtain purer nuclei. The resulting nuclear pellets were resuspended in 100 µL of NRO buffer (50 mM Tris at pH 7.5, 5 mM MgCl<sub>2</sub>, 150 mM KCl, 0.1% sarkosyl, 2 U/mL RNase inhibitor, 10 mM DTT) containing 0.1 mM ATP, GTP, CTP, and BrUTP (Sigma). Transcription was performed for 3 min on ice and then 5 min at room temperature. The reaction was stopped by addition of 600 µL of Trizol reagent, and RNA was extracted followed by the DNase I (Ambion) treatment to remove genomic DNA. The purified RNAs were incubat-

ed with 2 µg of anti-BrdU antibody (Sigma) or an equal amount of IgG antibody (Sigma) for 2 h at 4°C and then immunoprecipitated for 1 h with Dynabeads Protein G (Invitrogen) pre-coated with yeast tRNA (Sigma). Precipitated RNAs were extracted by Trizol reagent and used for cDNA synthesis and qPCR analysis. All measured samples were normalized to β-actin transcription.

### Biotin-labeled RNA pull-down

Biotinylated RNA pull-down assays were performed as described (Zhang et al. 2013b). DNA fragments of full-length EGFP with T7 promoter on its 5' end and fragment EGFP (76–495) with T7 promoters on both ends were in vitro transcribed with the biotin RNA-labeling mix (Roche) and T7 transcription kit (Promega). HeLa cells (10<sup>7</sup>) were collected and suspended in 1 mL of RIP buffer (25 mM Tris at pH 7.5, 150 mM KCl, 0.5 mM DTT, 0.5% NP40, 1 mM PMSF, 2 mM VRC, protease inhibitor cocktail) followed by sonication. After being centrifuged at 13,000 rpm for 15 min at 4°C, the supernatant was transferred into a new tube and pre-cleared with 40 µL of streptavidin Dynabeads for 20 min at 4°C. Next, 20 µg/mL yeast tRNA was added to block unspecific binding and incubated for 20 min at 4°C. The precleared lysate was divided into two parts, and each was supplemented with 2 µg of biotin-labeled *ss\_egfp* (full length of *egfp*) or *ds\_egfp* (an inverted repeated fragment of *egfp*) and incubated for 1.5 h followed by addition of 40 µL of streptavidin Dynabeads and incubation for another 1.5 h at room temperature. Beads were washed four times for 5 min with RIP buffer containing 0.5% sodium deoxycholate and boiled in 1× SDS loading buffer for 10 min at 100°C. The retrieved proteins were analyzed by Western blotting with anti-p54<sup>nrb</sup> (BD), anti-methyl-p54<sup>nrb</sup> (620me), and anti-PSF (Sigma).

### tRSA RNA pull-down

tRSA RNA pull-down assays were carried out as described (Iioka et al. 2011) with modifications. *IRAlus* from the 3' UTR of *Nicn1* were cloned into pcDNA3 with the tRSA tag at its 5' end. tRSA-*IRAlus* or tRSA was in vitro transcribed using the T7 transcription kit (Promega). Ten micrograms per reaction of synthetic RNAs was denatured for 5 min at 65°C and cooled to room temperature in the presence of PA buffer (10 mM Tris at pH 7.4, 10 mM MgCl<sub>2</sub>, 100 mM NH<sub>4</sub>Cl). Next, the RNAs were incubated with 40 µL of streptavidin Dynabeads for 20 min at 4°C in the presence of 2 U/mL RNasin (Promega). HeLa cells (10<sup>7</sup>) were collected and resuspended in 1 mL of lysis buffer (25 mM Tris at pH 7.4, 150 mM KCl, 0.5 mM DTT, 0.5% NP40, 1 mM PMSF, 2 mM VRC, protease inhibitor cocktail) followed by sonication. After centrifuging at 13,000 rpm for 15 min at 4°C, the supernatant was transferred into a new tube and pre-cleared with 40 µL of streptavidin Dynabeads for 20 min at 4°C followed by the addition of 20 µg/mL yeast tRNA for 20 min at 4°C. Beads prebound with tRSA-*IRAlus* RNA or tRSA RNA were incubated with precleared lysates for 4 h at 4°C followed by washing with lysis buffer containing 0.5% sodium deoxycholate. To harvest the protein complex, 50 µL of 1× SDS loading buffer was added and incubated for 10 min at 95°C and then analyzed by Western blotting.

### Dig-labeled RNA pull-down

Dig-RNA pull-down assays were carried out as described (Arab et al. 2014) with modifications. Two 10-cm dishes of cells expressing Flag-p54<sup>nrb</sup>-wt (MUT) or Flag-EGFP were used to immunoprecipitate with anti-Flag M2 (20 µL for each reaction) (Sigma). After immunoprecipitation and washing, one out of five beads was saved for Western blot. The rest were equilibrated in binding buffer (50 mM Tris at pH 8.0, 10% glycerol, 100 mM KCl, 5 mM

MgCl<sub>2</sub>, 10 mM β-mercaptoethanol, 0.1% NP-40) and incubated with 200 ng of Dig-labeled RNA in binding buffer for 1.5 h at room temperature. The Dig-labeled RNA was produced by Dig-labeled IVT of an *IRAlus* DNA fragment, which was amplified from the 3' UTR of *Nicn1*. After washing with immunoprecipitation buffer containing 500 mM NaCl, the bound RNA was extracted and analyzed by Northern blotting.

#### Computational pipeline for the analysis of genes containing 3' UTR *IRAlus* enriched in the *NEAT1* DNA CHART

A stringent pipeline was developed to identify 3' UTR *IRAlus* genes enriched by *NEAT1* DNA CHART. To identify 3' UTR *IRAlus* genes, *IRAlus* were identified by RepeatMasker (Tarailo-Graovac and Chen 2009). The 3' UTRs were defined in a RefSeq gene file. Next, the overlap region between *IRAlus* and the 3' UTR was calculated to ensure that *IRAlus* were located in the 3' UTRs. In total, 545 genes containing 3' UTR *IRAlus* were obtained. In MCF7 cells, 388 genes containing 3' UTR *IRAlus* were expressed (reads per kilobase per million mapped reads [RPKM] ≥ 2) by analyzing the available RNA sequencing data sets (MCF7 RNA-seq; Gene Expression Omnibus [GEO]: GSE47042) (Janky et al. 2014). To analyze the *NEAT1* DNA CHART-enriched *IRAlus*-containing genes, the *NEAT1* DNA CHART-seq data sets carried out in MCF7 cells (GEO: GSE47042) (West et al. 2014) were used to call peaks by MACS (version 1.4.2, 20120305) (Feng et al. 2012). One-hundred-forty-nine MCF cells expressed genes that contain 3' UTR *IRAlus* enriched by the *NEAT1* DNA CHART.

#### Acknowledgments

We are grateful to G. Carmichael for critical reading of the manuscript, M.R. Stallcup for CARM1 shRNA, and M. Person for MS analysis at the Protein and Metabolite Analysis Facility (University of Texas, Austin) supported by RP110782 (Cancer Prevention Research Institute of Texas).
